The Gulf of Mexico, despite its economic importance, is one of the world's least known major bodies of water, in regard both to mass water movements and to the abundance, distribution, ranges, and life histories of many species of fishes found within its boundaries. With the exception of several cruises of the Blake and Mabel Taylor in the late 1880's, the relatively small accumulation of scientific knowledge was confined largely to inshore areas. Although supporting a number of fisheries for many years, notably those for shrimp, snappers, oysters, and menhaden, the total fishery production of the Gulf has been considerably less than would normally be expected from an area of approximately 700,000 square miles. Recognizing the need for a more comprehensive general knowledge, it was decided to make a general oceanographic survey when the Gulf Fishery Investigations was established in the summer of 1950 at Galveston, Texas, by the Fish and Wildlife Service. The primary objective was to determine the spawning areas of various fishes. Studying the distribution of their eggs and larvae by means of plankton tows offered the best method for attaining this objective.

Data are presented in this report on the offshore plankton collections made in the Gulf from the M/V Alaska, research vessel of the Gulf Fishery Investigations. To aid in the comparison of data, the Gulf was divided arbitrarily into the eight subareas shown in figure 1 (see page 2). Ten cruises were made from March 1951 to July 1953. Originally it was planned to cover the entire Gulf annually in a series of three cruises, repeated each year. Unfortunately, the requisitioning of the Alaska for 24 weeks of sea-time disrupted the planned continuity.

As the distance between stations in the basic pattern (approximately 40 miles north and south, 100 miles east and west) seemed too great for obtaining representative plankton collections, I designed a sampler that could be towed at cruising speed between stations. It consisted essentially of a removable "Monel" wire-cloth

mesh net housed within a "Monel" tube. Details of construction are given in Fish and Wildlife Service Special Scientific Report--Fisheries No. 88. Designated as model G-IA, the sampler was fabricated and ready for use prior to the start of the second coverage of the Gulf (cruise 4-2A) in January 1952, and was operated successfully until inactivation of the Alaska in June 1953.

Continuing with the wire-cloth mesh principle, an all-metal net was designed and fabricated for making tows on station. Fundamentally a modified larger version of the G-IA model, this net was designated as model G-III, and is described in detail in the Special Scientific Report already cited.

It seemed logical to assume that the G-III sampler, towed for the same period of time at 4 to 5 knots, and with the same net opening, would catch substantially more plankton than a half-meter silk net, towed at one-fourth the speed. Moreover, we hoped that the increased speed, plus an opening unobstructed by a towing bridle, would result in the capture of the more agile planktonic forms.

Collecting operations in January 1952, during cruise 4-2A, afforded the first opportunity to compare the catching abilities of the G-III sampler and a conventional half-meter silk net. I used numbers and sizes of fish larvae ^{1/} as a basis for comparison.

Ten tows at 4 to 5 knots were made with the G-III sampler, 23 tows at approximately 1 knot were made with the half-meter net. All tows were of 30-minute duration. Both nets were fished horizontally, either at or within 10 meters of the surface. One G-III tow that yielded 959 larvae was considered atypical and was not used in the comparison. In the 9 remaining tows, the G-III net captured 1,334 fish larvae as

^{1/} The term "larvae", used in this paper, includes all immature forms.

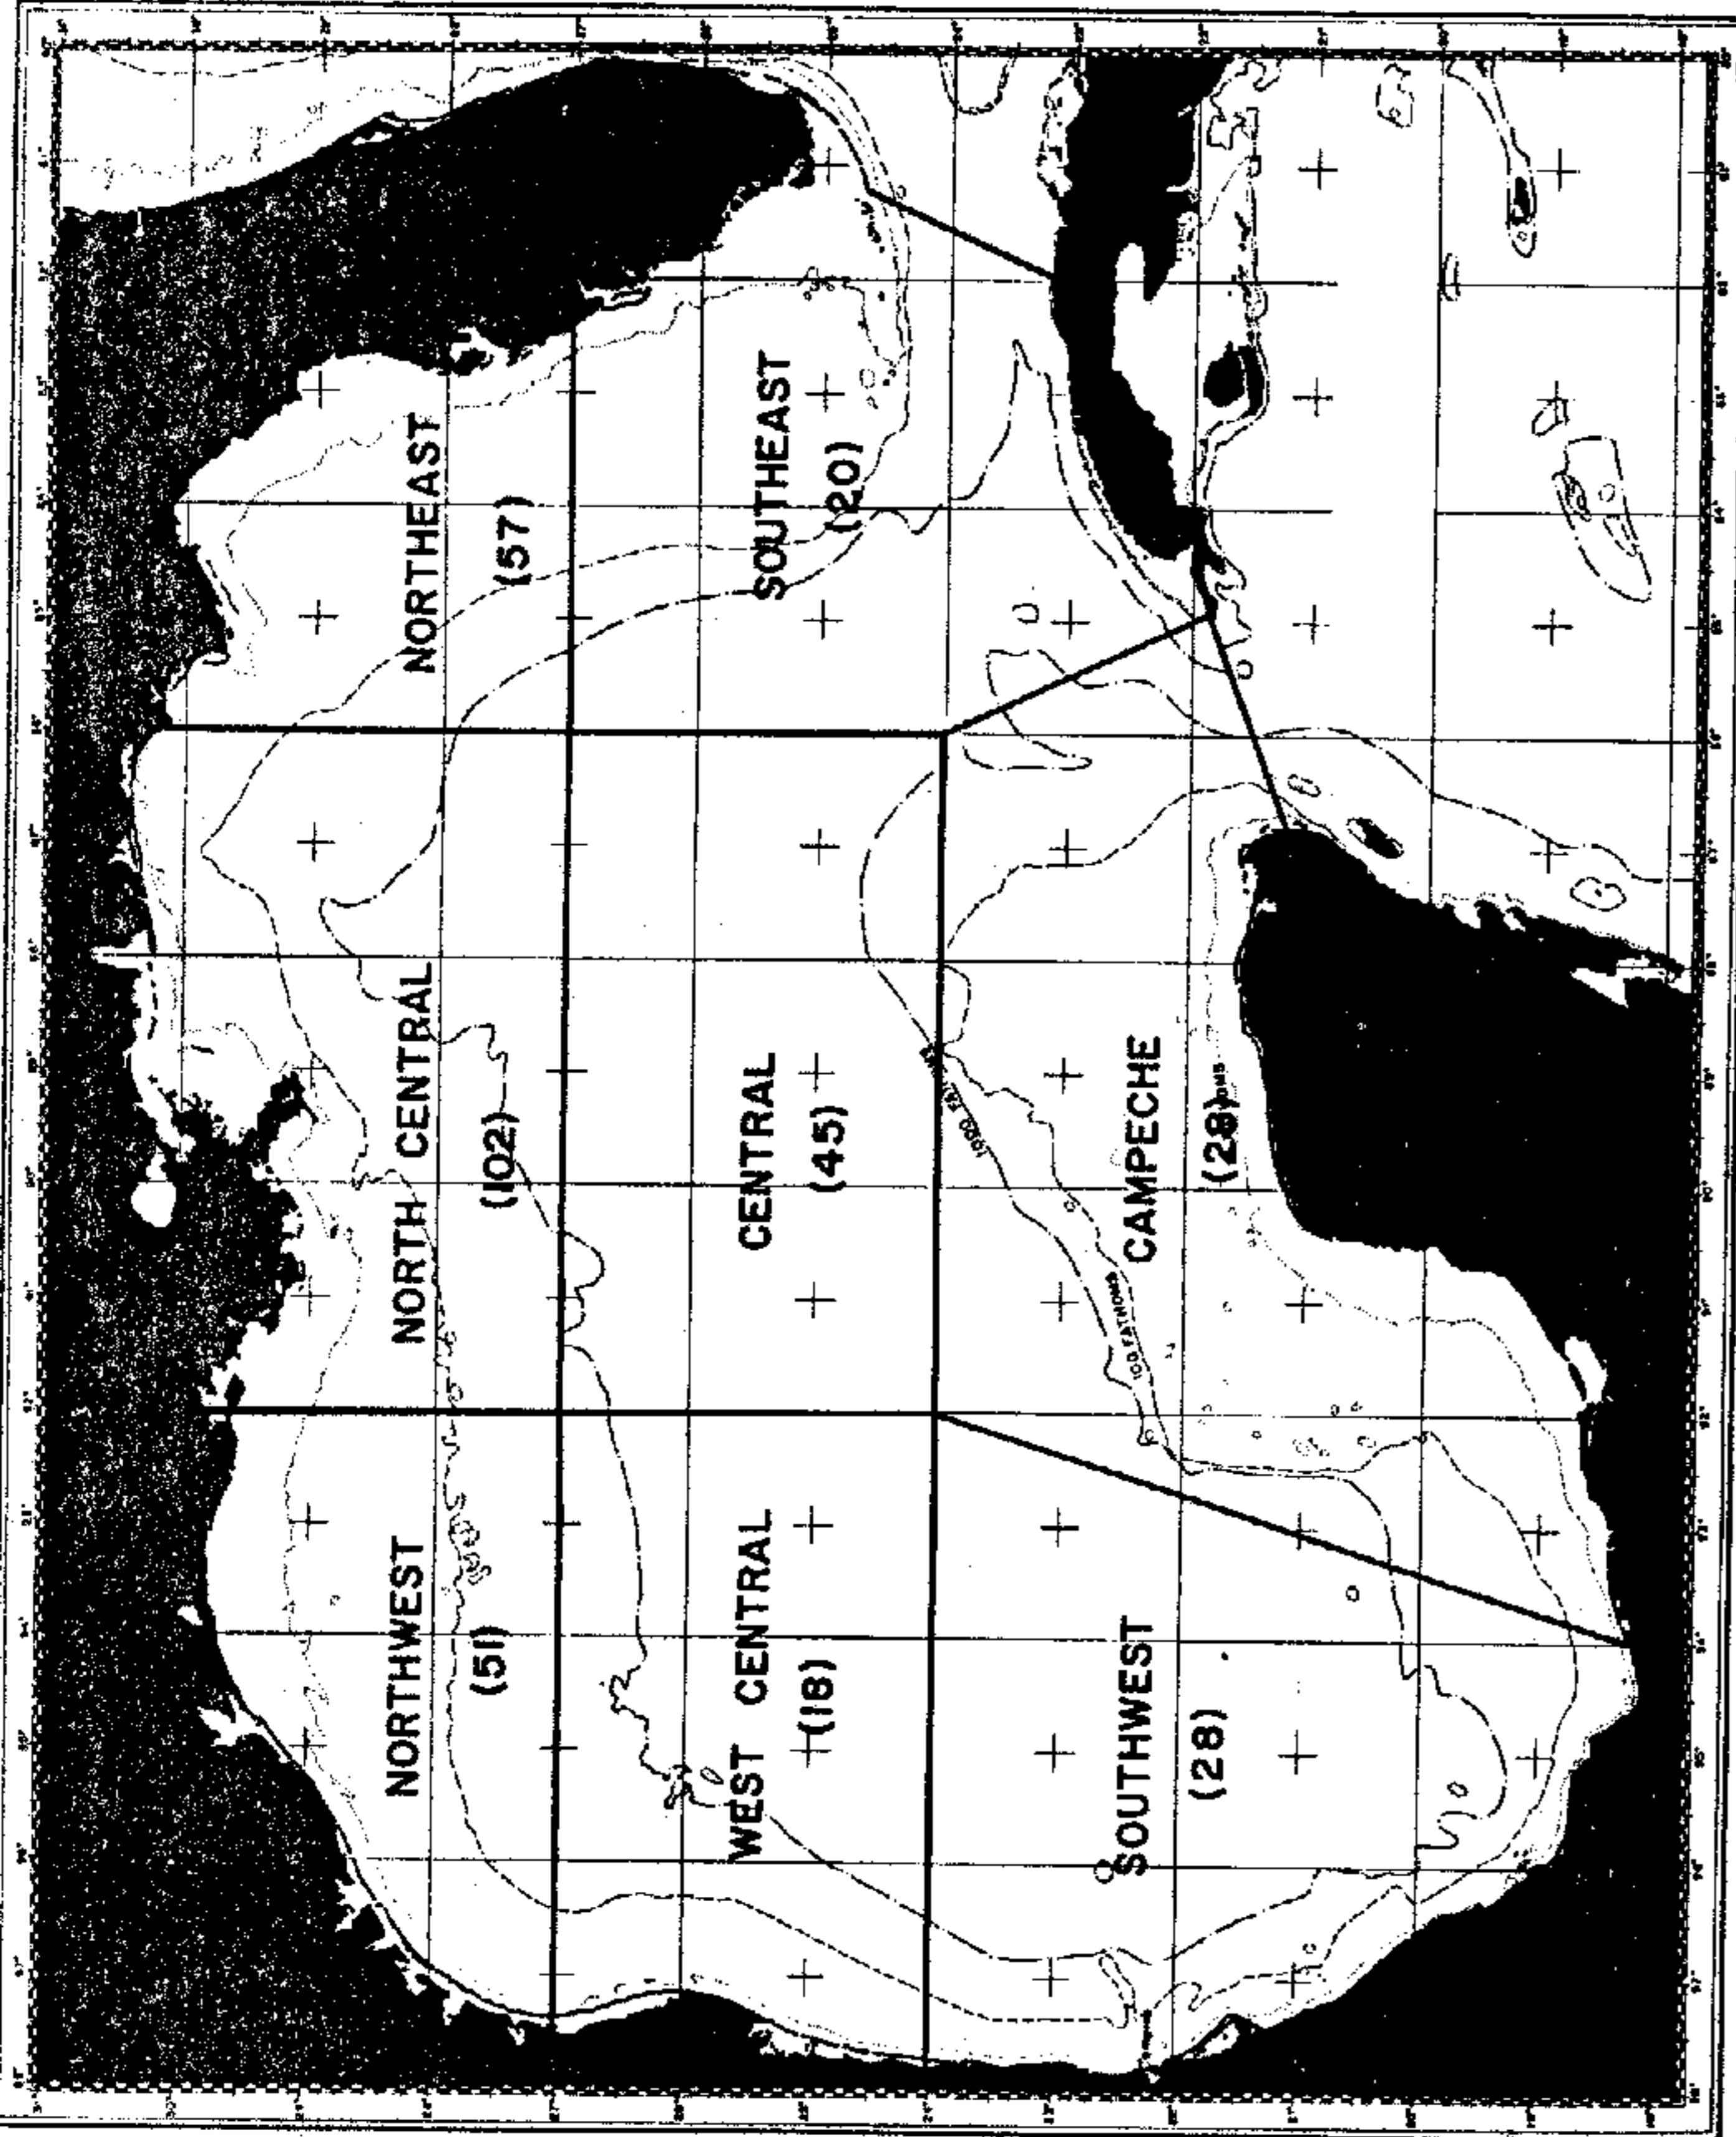

Figure 1.--Subareas into which the Gulf of Mexico was divided for comparison of offshore plankton data. Numbers in parenthesis represent the number of plankton tows made in each area.

compared to 414 larvae taken in 23 tows of the silk net. As shown in figure 2, the G-III samples contained larger specimens, as well as over three times the number of larvae. Contrary to what might be expected from the much greater towing speed and metal meshes of the G-III net, I found no difference in the condition of the catches of the two nets.

As a result of these findings and because of its other advantages (durability and ease of cleaning), the G-III sampler was used exclusively on subsequent cruises.

During the period of field work aboard the Alaska, a total of 449 tows were made with different types of gear, as follows:

Half-meter No. 10 silk net	94 tows
One-meter No. 10 silk net	9 tows
G-III Monel net No. 1 mesh	131 tows
G-IA Monel net No. 1 mesh	215 tows

Samples were first sorted for fish eggs and larvae. Prior to volume determination all gross forms (medusae, sargassum weed, etc.) were removed.

Volumes were obtained after the first four cruises by the following procedure:

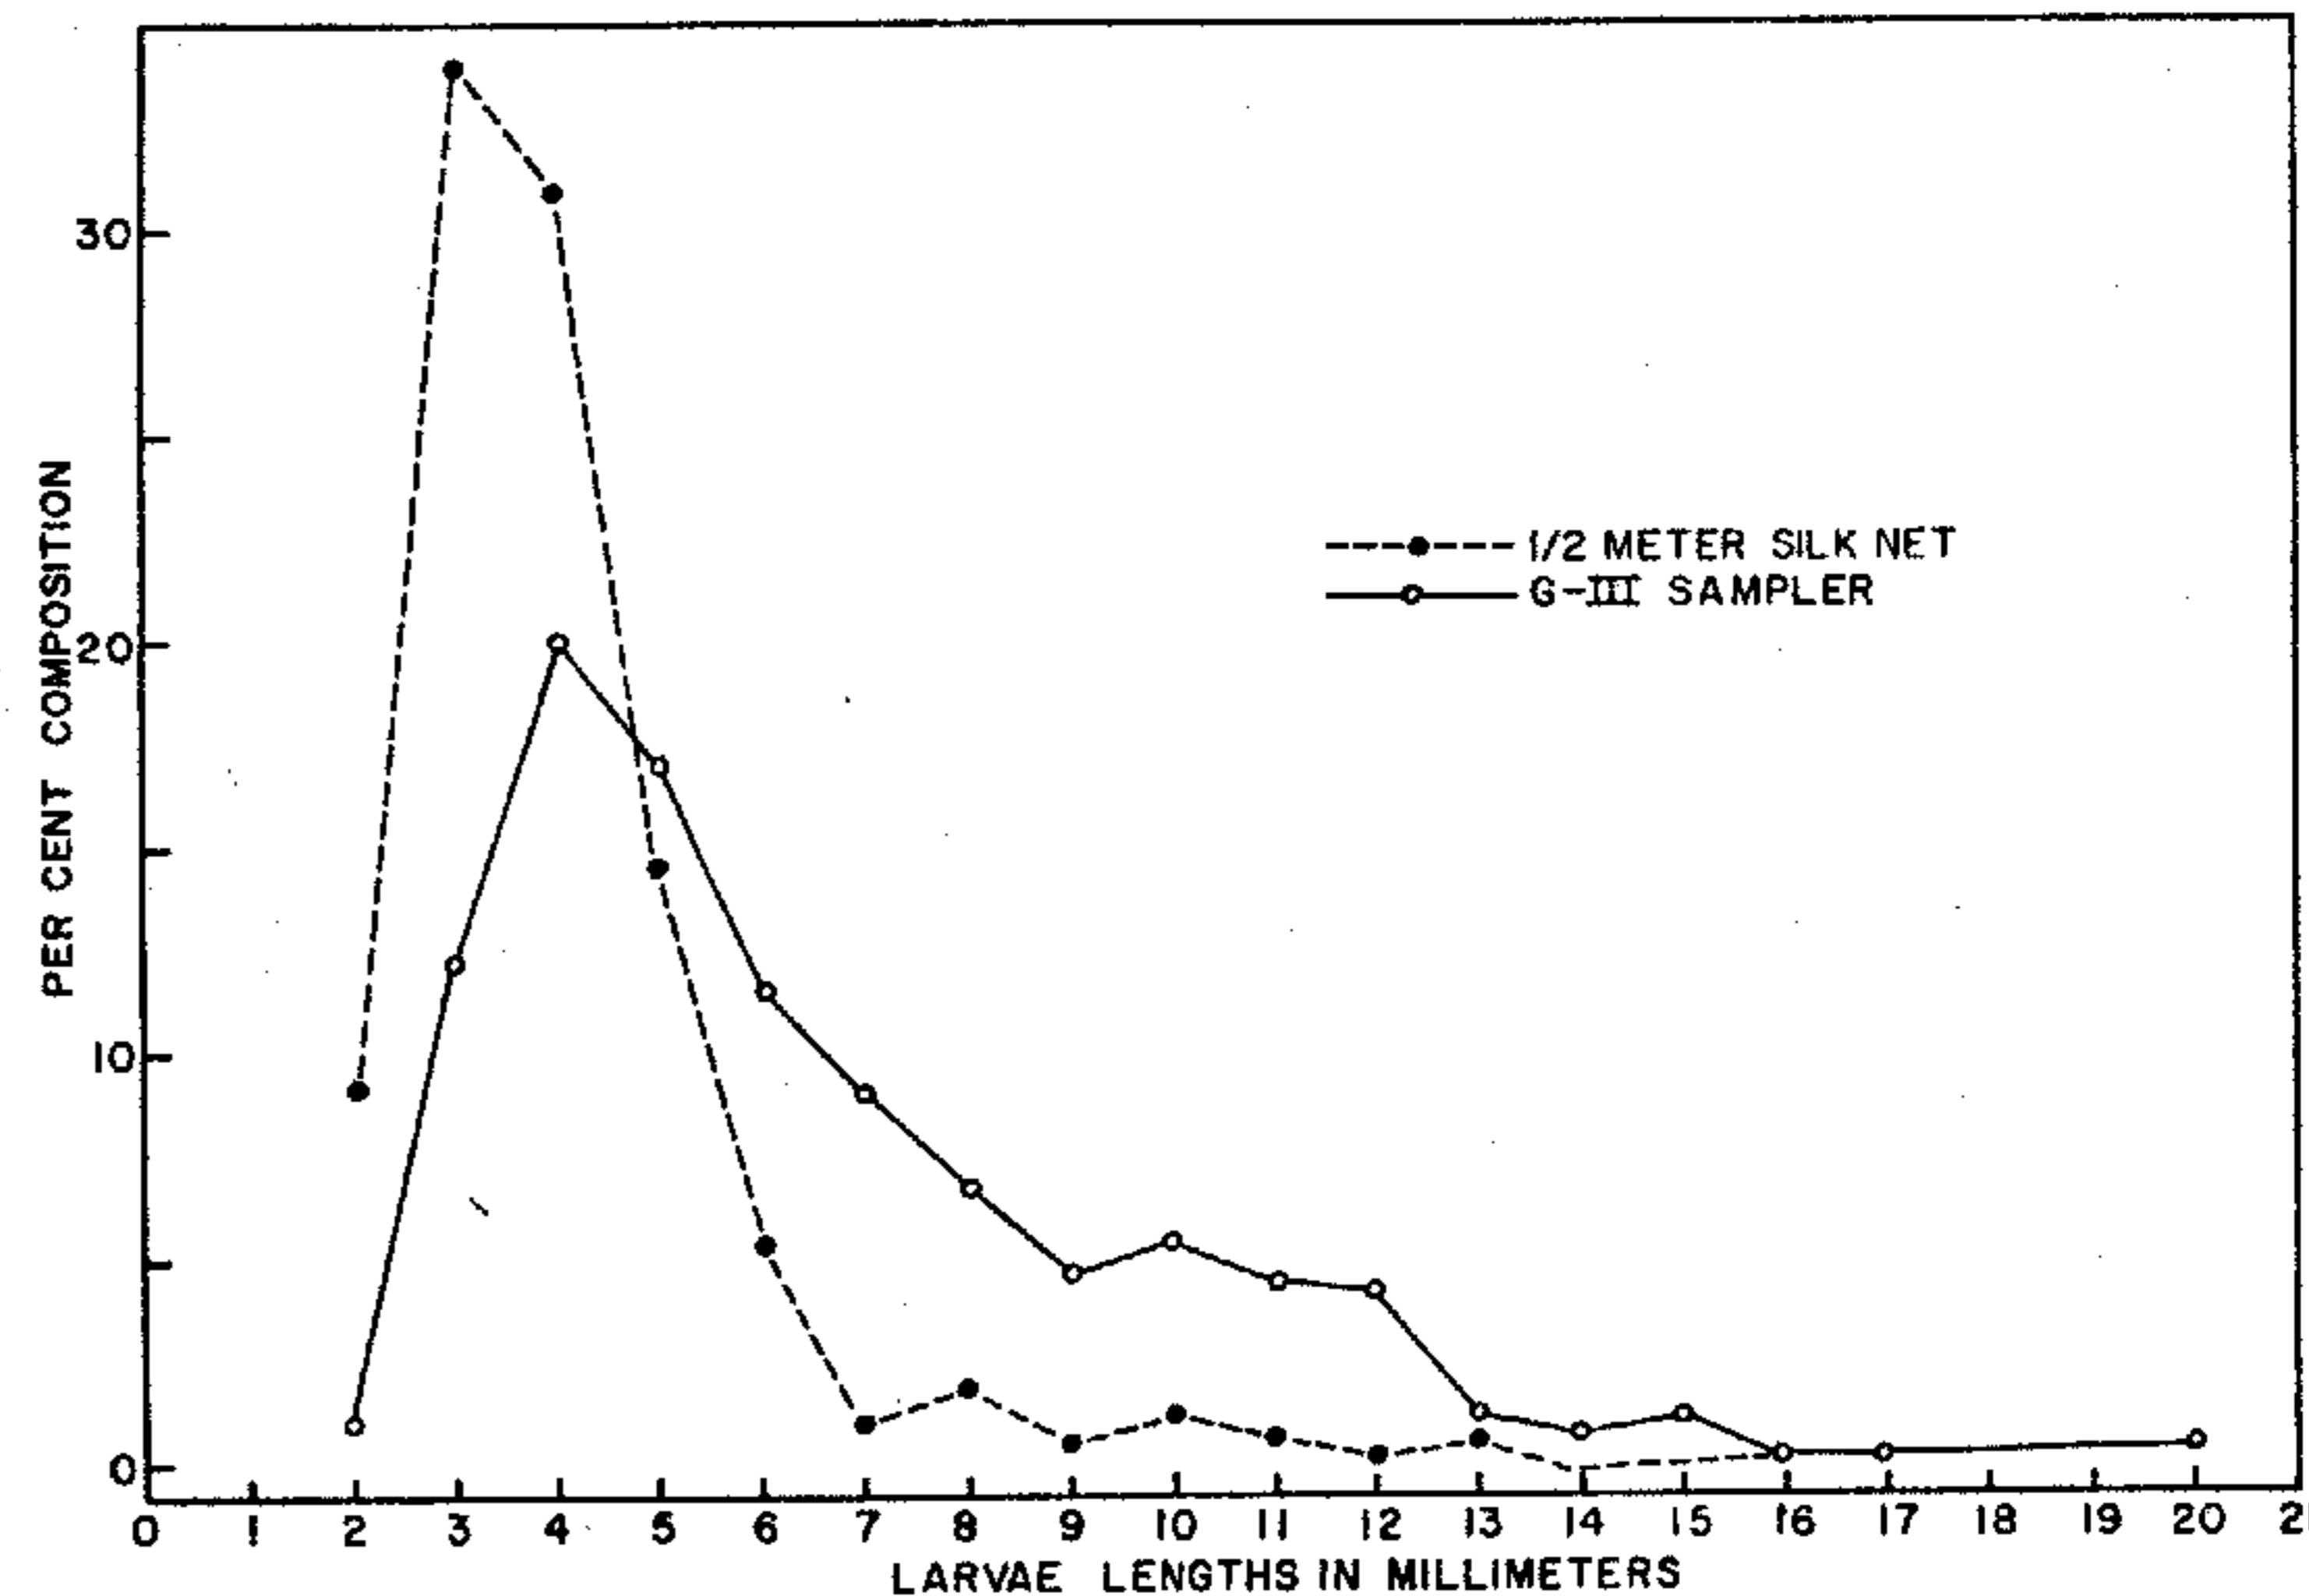

Figure 2.--Length frequencies by percent of larvae taken by a conventional half-meter silk net towed at one knot compared with those taken by the G-III sampler towed at 4 to 5 knots during Cruise 4-2A in January 1952.

1. Sample poured into graduate cylinder and reading noted to nearest milliliter.
2. Solution separated from plankton by force-filtering solution through a No. 1 Wratten disc filter by means of a vacuum-pump attachment.
3. Filtrate poured back into graduate and reading noted.
4. Volume is difference between the two readings.

For the first four cruises, however, we determined volumes by fractioning and centrifuging. To adjust these values to conform with those obtained by filtration, we ran, in duplicate, a series of plankton samples of different volume ranges through both methods to obtain the necessary conversion factors. All plankton volumes given in the tables are based on the first method described.

The volumes of water strained, as tabulated, were calculated from readings of the four Atlas current meters which were used throughout the Alaska cruises. As two meters were used with the G-III net on only one cruise, the readings for all quantitative hauls of this net were based on readings from the rear meter. Calibrations of the meters were obtained upon completion of field work by making duplicate tows in opposite directions at different speeds over a 4,500-foot course in calm water. The results of these calibrating runs which were used in the present report are as follows:

Meter No.	Liters per revolution
109	3.604
112	3.190
175	2.821
176	2.575

The following tables of data and their accompanying charts are tabulated according to gear and cruise. G-III hauls are numbered according to station. The results of G-III oblique hauls during cruise 5-2C (table 8) are in the same order of magnitude as those of horizontal tows, and thus received no special treatment.

In spite of the diversity of towing techniques and gear, the distribution of plankton by volume revealed a distinct pattern (tables 16 and 17), with the greater abundance appearing in catches made over the Continental Shelf.

In table 18 the catches of the two metal nets are compared on a quantitative basis. The G-III net, with its half-meter opening, caught substantially more of the active swimmers, but both models captured inactive forms (eggs) in nearly the same ratio. The table also points out the abrupt decrease in plankton abundance as the vessel moved seaward from waters over the Continental Shelf.

In considering the data presented in this report, it should be kept in mind that because of the emphasis placed on hydrography during the survey, and the relatively deep draft of the Alaska, few stations were taken in shallow water. Limited plankton collections subsequently made in shallow waters from smaller vessels in the vicinity of Galveston Island revealed a much higher concentration of plankton, especially in numbers of fish larvae, than appeared in the Alaska catches from farther offshore. It is probable, therefore, that intensive shallow-water collecting would reveal a higher potential of biological productivity for the inshore area of the Gulf than may be inferred from these tables.
